

Chemical Reactions & Writing Chemical Formulas

Chapter 15 Section 1

Chemical Change:

- Ice melting & water freezing are both examples of physical changes.
- During a physical change, a substance changes form, but remains the same substance.
- A chemical change turns 1 or more substances into different substances that usually have different properties (they now look different, smell different, act differently, etc.)
- Chemical change is really important & we use it everyday to make necessary substances like rubber, plastic, medicine, etc.

- A chemical reaction is material changing from a beginning mass to a resulting substance.
- The conclusion of a chemical reaction is that new material or materials are made, along with the disappearance of the mass that changed to make the new.
- This does not mean that new elements have been made.
- In order to make new elements, the nuclear contents must change, and that requires major amounts of energy.

So, what is a chemical reaction?

- What is a chemical reaction?
- A system of chemical changes that involve the breaking & reforming of bonds to create new substances.
- The result: a brand new substance

REACTANTS	→	PRODUCTS
- combined together		- newly formed bonds
- bonds break		- brand new substances
- atoms rearrange		

1. Here's Bill Nye: take notes

Signs of a chemical reaction

1. Bubbles - a gas formed

2. Precipitate - a solid formed

3. Color Change

4. Temperature change - energy changed

Parts of a Chemical Reaction

- In cooking, ingredients are combined to make food.
- In chemical reactions, reactants are combined to make products.
- The **reactants** are substances that are combined & changed in the reaction.
- The **products** are the new substances that result from the reaction.

Example #1: Hydrochloric Acid

- Reactants: hydrogen (H_2 - gas) + chlorine (Cl_2 -gas)
- The bonds break, the elements rearrange, and form new bonds with each other.
- Products: 2 HCl

Example #2: Baking soda & Vinegar

- What is the actual reaction between baking soda & vinegar?
- Reactants:
 - Sodium Bicarbonate (baking soda) $NaHCO_3$
 - Acetic Acid (vinegar) $HC_2H_3O_2$
- Now, break the bonds, rearrange the atoms, and what do you get???
- Products:
 - Sodium Acetate $NaC_2H_3O_2$
 - Carbon Dioxide CO_2
 - Water H_2O

ADD IT UP: How many total atoms are there?

_____ Hydrogen	_____ Sodium
_____ Oxygen	_____ Carbon

ADD IT UP:

How many total atoms are there?

$$NaHCO_3 + HC_2H_3O_2 \rightarrow NaC_2H_3O_2 + CO_2 + H_2O$$

Reactants:	Products:
_____ 5 Hydrogen	_____ 5 Hydrogen
_____ 1 Sodium	_____ 1 Sodium
_____ 5 Oxygen	_____ 5 Oxygen
_____ 3 Carbon	_____ 3 Carbon

A chemical reaction **rearranges the atoms of the reactants to form new compounds of the products.**

No new atoms are created

Chemistry & More Math

- Let's go back to our first example & add up the atoms from both sides of the equation.

Chemical equation	
Reactant side	Product side
$HC_2H_3O_2 + NaHCO_3 \rightarrow NaC_2H_3O_2 + H_2O + CO_2$	
3 carbon atoms 5 oxygen atoms 5 hydrogen atoms 1 sodium atom	3 carbon atoms 5 oxygen atoms 5 hydrogen atoms 1 sodium atom

- Notice that there is the exact same number of each type of atom on both sides of the equation.
- In other words, the equations are **balanced**.
- This proves something VERY important...

The Law of Conservation of Mass:

The mass of the reactants **equals** the mass of the products.

OR -

Mass is never **created nor destroyed**

OR

you can't get somethin' outta nothin'

Brain POP CONSERVATION OF MASS November 25, 2002 **SCORE: 10/10**

1. A chemical equation is a shorthand way to describe a chemical reaction. It shows the reactants on the left and the products on the right. The equation is balanced when the number of atoms of each element is the same on both sides.

2. The law of conservation of mass states that matter is neither created nor destroyed in a chemical reaction. The total mass of the reactants is equal to the total mass of the products.

3. In a chemical equation, the substances on the left are called reactants, and the substances on the right are called products. The arrow points from the reactants to the products.

4. The coefficients in a chemical equation are the numbers in front of the chemical formulas. They tell you how many molecules of each substance are involved in the reaction.

5. The subscripts in a chemical formula are the small numbers written below the element symbols. They tell you how many atoms of each element are in a molecule.

6. The state symbols in a chemical equation are (s) for solid, (l) for liquid, (g) for gas, and (aq) for aqueous solution.

7. The balanced chemical equation for the reaction of hydrogen and oxygen to form water is: $2H_2 + O_2 \rightarrow 2H_2O$.

8. The balanced chemical equation for the reaction of carbon and oxygen to form carbon dioxide is: $C + O_2 \rightarrow CO_2$.

9. The balanced chemical equation for the reaction of sodium and chlorine to form sodium chloride is: $2Na + Cl_2 \rightarrow 2NaCl$.

10. The balanced chemical equation for the reaction of iron and sulfur to form iron(II) sulfide is: $Fe + S \rightarrow FeS$.

2. Law of Conservation of Mass

Chemical Formulas/Equations:

- A molecule or compound consists of at least **two atoms that are chemically bonded**.
- The chemical formula of a molecule or compound states how **many atoms of each element** are in one of its molecules.
- This formula is similar to an algebraic formula in its use of symbols.
- The description of a compound with numbers and symbols is called a chemical formula.. Some formula can be quite complex.

- A **chemical equation** is a way to describe what goes on in a chemical reaction, the actual change in a material.
- Chemical equations are written with the **symbols** of materials to include elements, ionic or covalent compounds, aqueous solutions, ions, or particles.

- There is an **arrow** pointing to the right that indicates the action of the reaction.
- The materials to the left of the arrow are the **reactants**, or materials that are going to react.
- The materials to the right of the arrow are the **products**, or materials that have been produced by the reaction.

Chemical formulas

- Chemical formulas are designations of **molecules and compounds in shorthand notation**, similar to that used in Algebra.
- This is a way to show the exact number of atoms & compounds in a chemical reaction.
- We write the chemical equation for baking soda & vinegar as follows:
- $NaHCO_3 + HC_2H_3O_2 \rightarrow NaC_2H_3O_2 + CO_2 + H_2O$

Brain POP CHEMICAL EQUATIONS

Brain POP CHEMICAL EQUATIONS November 25, 2002 **SCORE: 10/10**

1. Matter can change its form, but the total mass of the matter remains the same. This is the law of conservation of mass.

2. The law of conservation of mass states that matter is neither created nor destroyed in a chemical reaction. The total mass of the reactants is equal to the total mass of the products.

3. In a chemical equation, the substances on the left are called reactants, and the substances on the right are called products. The arrow points from the reactants to the products.

4. The coefficients in a chemical equation are the numbers in front of the chemical formulas. They tell you how many molecules of each substance are involved in the reaction.

5. The subscripts in a chemical formula are the small numbers written below the element symbols. They tell you how many atoms of each element are in a molecule.

6. The state symbols in a chemical equation are (s) for solid, (l) for liquid, (g) for gas, and (aq) for aqueous solution.

7. The balanced chemical equation for the reaction of hydrogen and oxygen to form water is: $2H_2 + O_2 \rightarrow 2H_2O$.

8. The balanced chemical equation for the reaction of carbon and oxygen to form carbon dioxide is: $C + O_2 \rightarrow CO_2$.

9. The balanced chemical equation for the reaction of sodium and chlorine to form sodium chloride is: $2Na + Cl_2 \rightarrow 2NaCl$.

10. The balanced chemical equation for the reaction of iron and sulfur to form iron(II) sulfide is: $Fe + S \rightarrow FeS$.

EXAMPLES OF CHEMICAL CHANGES shown in chemical formulas:

- Chemical reactions, also called chemical changes, are not limited to happening in a chemistry lab.
- Here are some examples of chemical reactions with the corresponding chemical equations:

EXAMPLES OF CHEM CHANGES shown in chemical formulas:

- 1. A silver spoon tarnishes. The silver reacts with sulfur in the air to make silver sulfide, the black material we call tarnish.
$$2 \text{ Ag} + \text{S} \rightarrow \text{Ag}_2\text{S}$$
- 2. An iron bar rusts. The iron reacts with oxygen in the air to make rust.
$$4 \text{ Fe} + 3 \text{ O}_2 \rightarrow 2 \text{ Fe}_2\text{O}_3$$

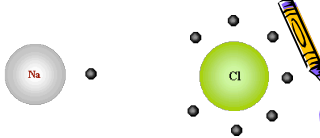

EXAMPLES OF CHEM CHANGES shown in chemical formulas:

- 3. Methane burns. Methane combines with oxygen in the air to make carbon dioxide and water vapor.
$$\text{CH}_4 + 2 \text{ O}_2 \rightarrow \text{CO}_2 + 2 \text{ H}_2\text{O}$$
- 4. An antacid (calcium hydroxide) neutralizes stomach acid (hydrochloric acid).
$$\text{Ca}(\text{OH})_2 + 2 \text{ HCl} \rightarrow \text{CaCl}_2 + 2 \text{ H}_2\text{O}$$

MORE Chemical Equations - Examples

Here are some common equations:

- **Water:** $2\text{H}_2 + \text{O}_2 \rightarrow 2\text{H}_2\text{O}$
- **Carbon Dioxide:**
 $\text{CH}_4 + 2\text{O}_2 \rightarrow \text{CO}_2 + 2\text{H}_2\text{O}$
- **Photosynthesis:**
 $6\text{CO}_2 + 6\text{H}_2\text{O} \rightarrow \text{C}_6\text{H}_{12}\text{O}_6 + 6\text{O}_2$

• **Salt:** $2\text{Na} + \text{Cl}_2 \rightarrow 2\text{NaCl}$

• the poisonous green chlorine gas is combined with the explosive metal sodium to form the white salt crystals we use in our food.

Complex formulas

- Just as in Algebra, you can use parentheses to separate parts in a complex formula. One example is the formula for nitroglycerin, a highly explosive substance.
$$\text{C}_3\text{H}_5(\text{NO}_3)_3$$
- This formula shows that nitroglycerin consists of 3 atoms of C, 5 atoms of H and then 3 NO_3 nitrate ions. If the parentheses were not used, you might have a formula like:
$$\text{C}_3\text{H}_5\text{N}_3\text{O}_9$$

Complex formulas

- The number of atoms for each element would be correct, but it wouldn't help to describe the true structure of the nitroglycerin molecule.
- Remember that molecules are 3-dimensional collections of atoms. In more complex molecules--especially in organic substances--the configuration becomes important.

- Carbon dioxide is CO_2 , which means there is one atom of carbon and two atoms of oxygen in the molecule.

Number of molecules

- To show the **number of molecules**, a full sized number is located in front of the molecule.
- This is called a **coefficient**.
- For example 4 molecules of carbon dioxide is designated as: 4CO_2
- This means there are a total of 4 C atoms and 8 O atoms in the combination.
- A way to remember this--taken from Algebra--is to think of it as $4 \times (\text{CO}_2)$.

BALANCING EQUATIONS

- Now comes the fun part, balancing the reaction.
- The **Law of Conservation of Mass** states that in a chemical reaction there **is no loss of mass**.
- Each type of element will have the same amount before the reaction and after the reaction, or as reactant and product.
- But you can't change the materials that participate in the reaction, so you must write an integer coefficient in front of (to the left of) each material in the reaction to make sure every type of atom has the same number on each side of the reaction.

BALANCING EQUATIONS

- 1. Nitrogen gas plus hydrogen gas under pressure and at high temperature turn into ammonia.
- First write the materials correctly. Nitrogen and hydrogen are diatomic gases. Ammonia is a binary covalent memory item.
- The nitrogen and hydrogen are the reactants, and the ammonia is the product.
- Leave room for the coefficients in front of the materials.

- 2. You can begin with either the nitrogen or the hydrogen.
- There are two nitrogen atoms on the left and only one on the right.
- In order to balance the nitrogen atoms, place a 2 in front of the ammonia.

- 3. There are two hydrogens on the left and six on the right. We balance the hydrogens by placing a 3 in front of the hydrogen gas.

- 4. Now go back and check to make sure everything is balanced. There are 2 nitrogen and 6 hydrogens on both sides of the reaction. It is balanced.
- There is no coefficient shown in front of the nitrogen. There is no need to write ones as coefficients.

The reaction equation is:

THE 4 RULES OF CHEMICAL REACTIONS

- 1. Chemical reactions are processes in which **atoms are rearranged** into different combinations of molecules.
- 2. Reactants interact, change bonds, and **form products with different chemical properties**.
- 3. In a reaction, the **number of atoms stays the same**, no matter how they are arranged, so their total mass stays the same.
- 4. Chemical reactions **usually liberate/release or absorb heat**. (which we will talk about more tomorrow!)

In conclusion

- The number of atoms of each element in a chemical formula is designated by the small number behind each element symbol.
- If there is no number, it is assumed there is only one of that element.
- A large number in front of a compound designates how many units there are of that compound.
- Parentheses can be used to designate a special structure, where other molecules are attached to the larger, complex molecule.

3. Everybody sing....

Don't Break The Law

Music & Lyrics © 2007, Mark Rosengarten
