

Review: 1. What are the 5 states of matter?

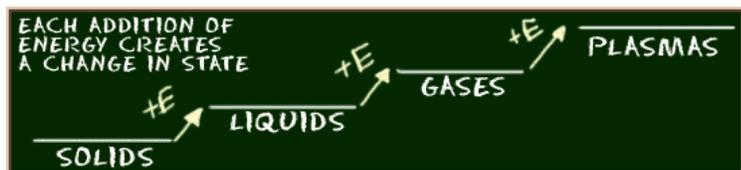

2. How do the molecules move in the 3 main states?

**States & Phases**

Each of the 5 states is also known as a \_\_\_\_\_. Elements and compounds can move from one phase to another phase when special physical forces are present. One example of those forces is temperature. The phase or state of matter can change when the temperature changes. Generally, as the \_\_\_\_\_ rises, matter moves to a more active state.

**It's All About the Energy**

It's totally possible to go from a solid to a liquid to a gas, and back again. These are called state changes or phase changes. But it's all about the energy. Which state you go to depends on whether you are adding or removing energy. During a change of state, the energy of the substance \_\_\_\_\_.

This is related to how the particles move. If you add energy to a substance, the particles \_\_\_\_\_. If you remove energy from a substance, the particles \_\_\_\_\_. In fact, \_\_\_\_\_ is a measure of the speed of particles. Each state has a different energy "requirement". In order to be a plasma, you need a ton of energy because your particles better be moving! In order to be a solid or BEC, the particles are fine just chilling - so they don't need as much energy.

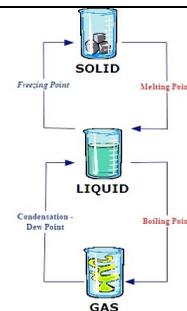

**Two Types of Energy Change**

1. \_\_\_\_\_: energy is absorbed, or taken in, by a substance (absorbs heat – feel \_\_\_\_\_)
2. \_\_\_\_\_: energy is removed, or taken out, of a substance (releases heat – feels \_\_\_\_\_)

**Melting:** \_\_\_\_\_ to \_\_\_\_\_  
Let's start with an ice cube. This ice cube starts off as a solid. When we add heat (energy), it begins to melt into a liquid.

**How does melting work?** When a substance is heated, it absorbs energy and its atoms and molecules begin oscillating, or moving. Eventually, they move so much that they break some of their bonds of attraction which are holding them tightly in place. They move so vigorously that they begin to move past one another, flowing like a liquid. Thus, as energy is being absorbed, this is an \_\_\_\_\_ change.

**Melting Point** The \_\_\_\_\_ of a substance is the temperature at which a substance changes from the solid to liquid. Melting points range from low temps to very high temps. The melting point is typically a very unique property of a substance. We can use melting points to determine the identity of a substance.

**Vaporization:** \_\_\_\_\_ to \_\_\_\_\_  
Now let's take that water and put it into a pot over flame. Eventually, the water will start to boil and turn into a gas. \_\_\_\_\_ is the name of this process.  
Boiling is vaporization that occurs throughout a liquid. The temperature at which a liquid boils is its \_\_\_\_\_. The boiling point of water = \_\_\_\_\_.

**A special kind of Vaporization**

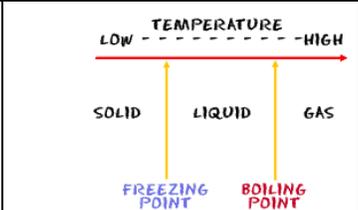

\_\_\_\_\_ is vaporization that occurs at the surface of the liquid, below its boiling point. This happens because as the liquid is heated, some particles manage to escape early, before the boiling point is reached. When they escape, they leave the surface of the liquid to become a gas. Sweating is a natural process used by humans to cool off. When we sweat, the water absorbs the heat (energy) and gives the sensation of cooling.

**How does Boiling work?** When you're heating a pot of water, the heat energy is making the water molecules move faster and faster. When enough thermal energy (heat) is added, the intermolecular forces in the substance are completely overcome and the liquid becomes a gas.

**Condensation to:** \_\_\_\_\_ Condensation happens when several gas molecules come together and form a liquid. It all happens because of a loss of energy. Gases are really excited atoms. When they lose energy, they slow down and begin to collect. They can collect into one drop. Water condenses on the lid of your pot when you boil water. It cools on the metal and becomes a liquid again. You would then have a condensate.

**Freezing:** \_\_\_\_\_ **to** \_\_\_\_\_  
 Now let's reverse melting. Let's take our liquid water and put it in the freezer - where it will turn into a solid. The temperature at which a liquid changes into a solid is its \_\_\_\_\_ point. Freezing is an \_\_\_\_\_ change, because energy is taken out of the substance.

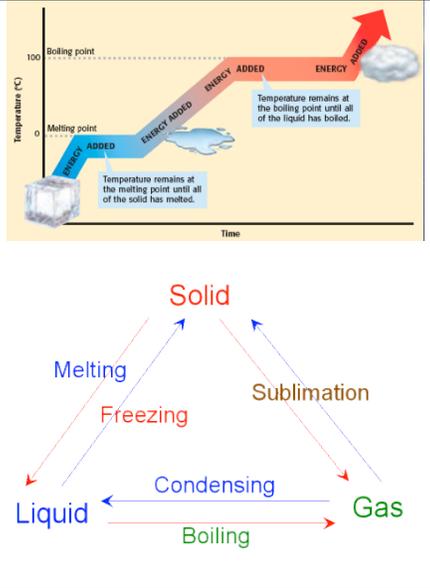

**How does freezing work?**  
 As energy leaves, the particles begin to slow down. They become pulled into a more ordered arrangement, or a locked position. Or basically, into a solid!

**Sublimation:** \_\_\_\_\_ **Directly to** \_\_\_\_\_  
 This phase change totally bypasses the liquid state. This is an \_\_\_\_\_ change, because the only way this can happen is if the atoms are suddenly moved very far apart (think of how much space a gas wants to take up). And the only way the atoms can be moved far apart from one another is if the attraction between particles is completely overcome...which requires lots of energy!

**Example of Sublimation**  
 \_\_\_\_\_ is an example of sublimation. Dry ice is solid carbon dioxide (CO<sub>2</sub>). Carbon Dioxide is typically found as a gas. When it is frozen into a solid, it turns directly into a gas and totally skips the liquid stage.

**Two More Really Important Points... First,** all phase changes are \_\_\_\_\_ changes, not chemical changes. This is because the substance stays the same before and after the state change. It is just changing its shape, not itself! **Second,** the temperature of a substance does NOT change during a phase change. It only changes before or after the change.

| Summarizing the Changes of State |                               |                            |   |
|----------------------------------|-------------------------------|----------------------------|---|
| Change of state                  | Direction                     | Endothermic or exothermic? | Example   |
| <input type="text"/>             | solid → liquid                | endothermic                | Ice melts into liquid water at 0°C.                       |
| <input type="text"/>             | liquid → solid                | <input type="text"/>       | Liquid water freezes into ice at 0°C.                     |
| Vaporization                     | liquid → gas                  | endothermic                | Liquid water vaporizes into steam at <input type="text"/> |
| Condensation                     | <input type="text"/> → liquid | exothermic                 | Steam condenses into liquid water at 100°C.               |
| Sublimation                      | solid → gas                   | <input type="text"/>       | Solid dry ice sublimates into a gas at -78°C.             |

**BrainPop: Matter Changing States**

- What are the states of matter? A. Solid, Liquid, Gas  
 B. Ice, water, steam C. Temperature, pressure, energy
- What is matter? A. Anything that is visible B. Anything that has mass & takes up space C Anything that reflects light
- What type of change is a change of state?  
 A. Physical change B. Chemical change C. Molecular change
- How do the molecules in a solid move?  
 A. They bounce off one another randomly  
 B. They flow past one another C. They vibrate
- The heat required to change a solid into a liquid is its:  
 a. Heat of vaporization B Heat of condensation C Heat of fusion
- What is the melting point of water?  
 A. 0 degrees Fahrenheit B. 0 degrees Celsius C. 0 Kelvin
- The heat required to change a liquid into a gas is its:  
 A. heat of steam B heat of gaseousness C Heat of vaporization
- What is it called when a solid turns directly into a gas?  
 A. Sublimation B. Vaporization C Melting
- What is dry ice? A. Frozen water B Solid carbon dioxide  
 C Ice that gives off water vapor
- How do the molecules of a gas behave?  
 A. They vibrate in place B. The clump together  
 C. They bounce around randomly
